4	0.0	0.930556	0.326733	0.0	1	0	1	0	

Preparing Data for Clustering

To prepare the data for clustering, I will create a new DataFrame `X` by copying all columns from the existing `df` DataFrame.

```
X = df.copy()
display(X.head())
```

	SeniorCitizen	tenure	MonthlyCharges	IsNewCustomer	gender	Dependents	PhoneService	MultipleLines	Interne
0	0.0	0.013889	0.069307	0.0	0	0	0	0	
1	0.0	0.569444	0.069307	0.0	1	0	1	0	
2	0.0	0.722222	0.009901	0.0	0	1	1	0	
3	0.0	0.013889	0.574257	0.0	0	0	1	0	
4	0.0	0.930556	0.326733	0.0	1	0	1	0	

Determine Optimal Number of Clusters

To perform the Elbow Method, I will import KMeans from sklearn.cluster and matplotlib.pyplot for plotting. Then, I will iterate through a range of possible cluster numbers (1 to 10), fit a KMeans model for each, and store the inertia. Finally, I will plot the inertia values against the number of clusters to visualize the elbow point.

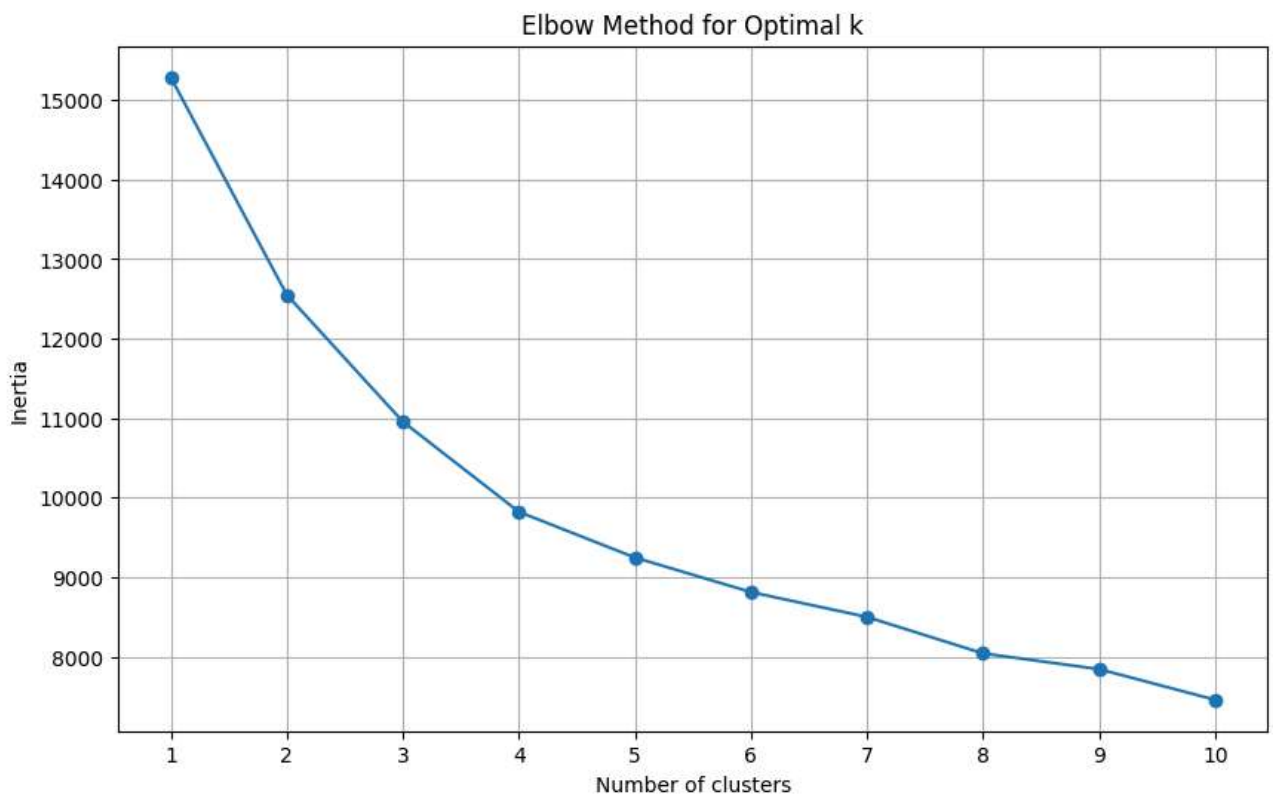
```
from sklearn.cluster import KMeans
import matplotlib.pyplot as plt

inertia = []

for i in range(1, 11): # Looping from 1 to 10 clusters
    kmeans = KMeans(n_clusters=i, random_state=42, n_init=10)
    kmeans.fit(X)
    inertia.append(kmeans.inertia_)

plt.figure(figsize=(10, 6))
plt.plot(range(1, 11), inertia, marker='o')
```

```
plt.title('Elbow Method for Optimal k')
plt.xlabel('Number of clusters')
plt.ylabel('Inertia')
plt.xticks(range(1, 11))
plt.grid(True)
plt.show()
```



Apply K-Means Clustering

Based on the Elbow Method plot, the optimal number of clusters appears to be 4, as this is where the rate of decrease in inertia significantly slows down. I will define `k_optimal` as 4 and then instantiate and fit the KMeans model to the `X` DataFrame.

```
k_optimal = 4
kmeans = KMeans(n_clusters=k_optimal, random_state=42, n_init=10)
kmeans.fit(X)
X['Cluster'] = kmeans.labels_
print(f"K-Means clustering completed with {k_optimal} clusters.")
display(X.head())
```

```
K-Means clustering completed with 4 clusters.
```

Visualize Customer Segments

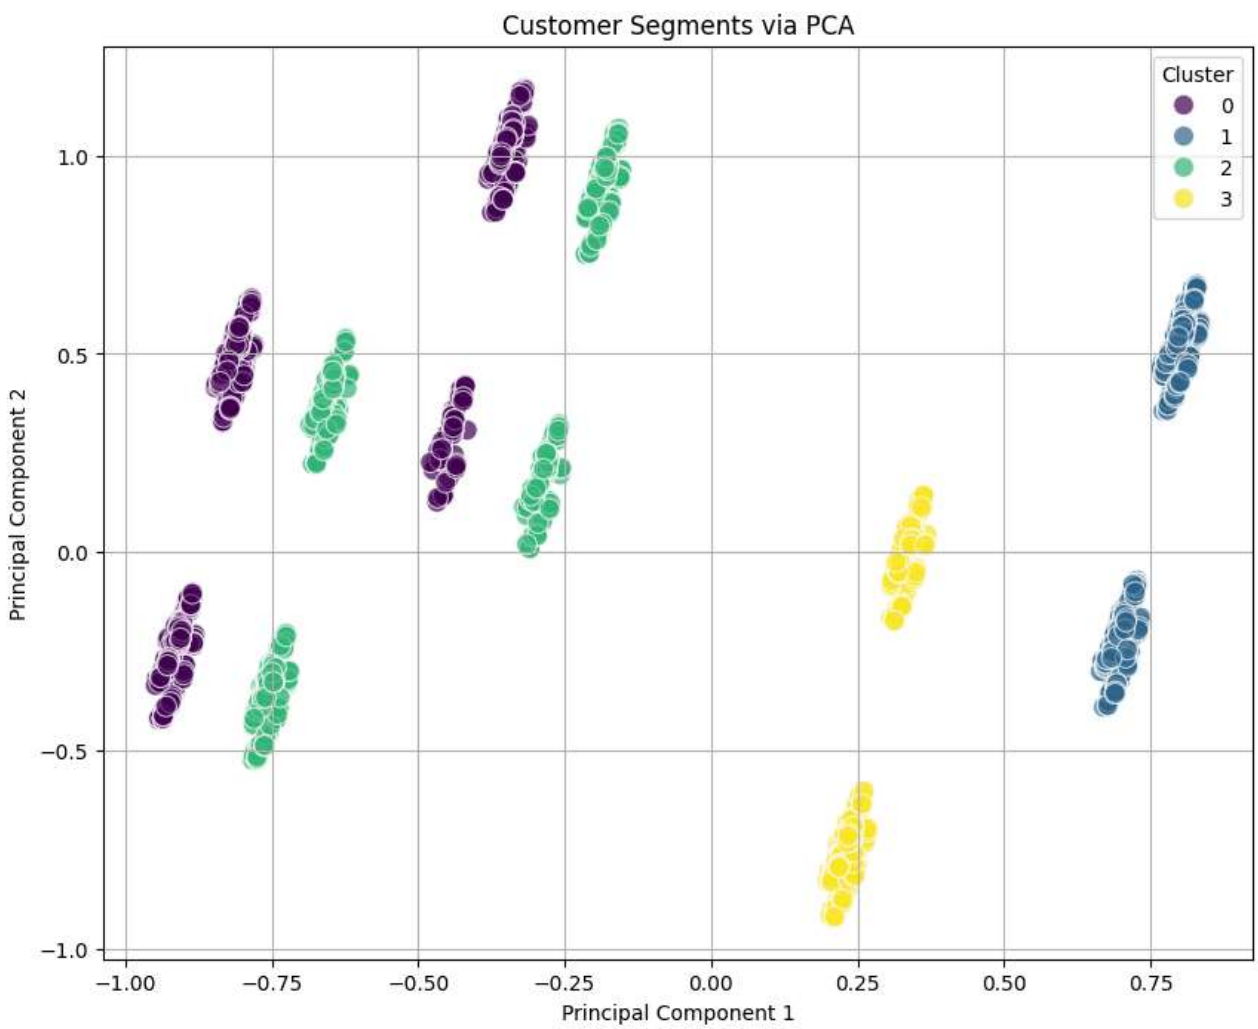
To visualize the customer segments, I will first apply PCA to reduce the dimensionality of the data to two components. Then, I will create a scatter plot of these components, coloring each point by its assigned cluster. This requires importing PCA, creating a new DataFrame for the PCA results, and using matplotlib or seaborn for plotting.

```
from sklearn.decomposition import PCA
import matplotlib.pyplot as plt
import pandas as pd
import seaborn as sns

pca = PCA(n_components=2, random_state=42)
X_pca_transformed = pca.fit_transform(X.drop('Cluster', axis=1))

X_pca = pd.DataFrame(data=X_pca_transformed, columns=['PC1', 'PC2'])
X_pca['Cluster'] = X['Cluster']

plt.figure(figsize=(10, 8))
sns.scatterplot(x='PC1', y='PC2', hue='Cluster', data=X_pca, palette='viridis', s=100, alpha=0.7)
plt.title('Customer Segments via PCA')
plt.xlabel('Principal Component 1')
plt.ylabel('Principal Component 2')
plt.legend(title='Cluster')
plt.grid(True)
plt.show()
```



Analyze Cluster Characteristics

To understand the characteristics of each cluster, I will group the DataFrame by the 'Cluster' column and calculate the mean of all features for each cluster, then display the result.

```
cluster_means = X.groupby('Cluster').mean()
display(cluster_means)
```

Start coding or generate with AI.

Summary of Clusters

- **Optimal Number of Clusters**: The Elbow Method indicated that the optimal number of clusters for this dataset is 4.
- **Customer Segment Descriptions**:
  - **Cluster 0**: This segment predominantly consists of new customers (`IsNewCustomer` mean of 1.0) who generally have short tenure. They have relatively low monthly charges and are less likely to churn. This group includes a mix of internet service users and non-users, with a tendency towards month-to-month contracts.
  - **Cluster 1**: This segment is characterized by exclusive internet service users (`InternetService` mean of 1.0 for relevant columns, 0.0 for others), high monthly charges, and a higher churn rate compared to other clusters (e.g., `Churn` mean of 0.70). They tend to be long-term customers with longer tenure and often have dependents.
  - **Cluster 2**: This segment primarily consists of customers without internet service (`InternetService` mean of 0.0 for all relevant columns). They have very low monthly charges, very low churn, and long tenure. They mostly have one-year or two-year contracts.
  - **Cluster 3**: This segment has high monthly charges, moderate tenure, and a significant churn rate (e.g., `Churn` mean around 0.52). They typically use fiber optic internet service and tend to be senior citizens, often without dependents. They are more likely to be on month-to-month contracts.
- **Review of Visualizations**:
  - The Elbow Method plot clearly showed a noticeable "elbow" at 4 clusters, supporting the selection of `k=4`.
  - The PCA scatter plot effectively visualized the four customer segments in a 2D space. The clusters appear to be reasonably separated, indicating distinct groups.

Data Analysis Key Findings

- The data was successfully prepared for clustering by creating a copy of the original DataFrame.
- The Elbow Method was applied, and a clear "elbow" was observed at 4 clusters, indicating that four is the optimal number of segments.
- A K-Means model was trained using 4 clusters, and each customer was successfully assigned to one of these clusters.
- Principal Component Analysis (PCA) was used to reduce the data dimensionality to two components, which allowed for an effective visualization of the distinct customer segments.

- Analysis of cluster means revealed unique characteristics for each segment:
  - **Cluster 0** consists of new customers with short tenure, low charges, and low churn.
  - **Cluster 1** represents internet-only users with high charges and high churn, typically long-term customers with dependents.
  - **Cluster 2** includes non-internet users with very low charges, very low churn, and long tenure, often on longer contracts.
  - **Cluster 3** is composed of high-charge, moderate-tenure customers with significant churn, frequently senior citizens using fiber optic internet on month-to-month contracts.

Prepareing the Data for ANN Modelling

```
y = X['Churn']
X_data = X.drop('Churn', axis=1)

from sklearn.preprocessing import StandardScaler
scaler = StandardScaler()
X_scaled = scaler.fit_transform(X_data)

from sklearn.model_selection import train_test_split
X_train, X_test, y_train, y_test = train_test_split(X_scaled, y, test_size=0.2, random_state=42)

print("Data preparation for ANN complete.")
print(f"X_train shape: {X_train.shape}")
print(f"X_test shape: {X_test.shape}")
print(f"y_train shape: {y_train.shape}")
print(f"y_test shape: {y_test.shape}")
```

```
Data preparation for ANN complete.
X_train shape: (5634, 13)
X_test shape: (1409, 13)
y_train shape: (5634,)
y_test shape: (1409,)
```

Define ANN Architecture

Before defining the ANN architecture. I will import necessary Keras modules, construct the sequential model with specified layers and activations, compile it with the given loss, optimizer, and metrics, and then print the model summary.

```
import tensorflow as tf
from tensorflow.keras.models import Sequential
from tensorflow.keras.layers import Dense
from tensorflow.keras.metrics import Precision, Recall, AUC

# Get the number of features from X_train
input_shape = X_train.shape[1]

# Initialize the Sequential model with an explicit Input layer
model = Sequential([
    tf.keras.Input(shape=(input_shape,), name='input_layer'), # Explicit Input layer
    Dense(32, activation='relu', name='hidden_layer_1'),
    Dense(16, activation='relu', name='hidden_layer_2'), # Renamed for clarity, was hidden_layer_1
    Dense(1, activation='sigmoid', name='output_layer')
])

# Compile the model
model.compile(
    optimizer='adam',
    loss='binary_crossentropy',
    metrics=['accuracy', Precision(), Recall(), AUC(name='auc_score')]
)
```

```
# Display the model summary
print("ANN Model Summary:")
model.summary()
```

```
ANN Model Summary:
Model: "sequential_6"
```

Layer (type)	Output Shape	Param #
hidden_layer_1 (Dense)	(None, 32)	448
hidden_layer_2 (Dense)	(None, 16)	528
output_layer (Dense)	(None, 1)	17

```
Total params: 993 (3.88 KB)
Trainable params: 993 (3.88 KB)
```

```
from tensorflow.keras.callbacks import EarlyStopping, ReduceLROnPlateau
import matplotlib.pyplot as plt

# Define callbacks
early_stopping = EarlyStopping(monitor='val_loss', patience=10, restore_best_weights=True)
reduce_lr = ReduceLROnPlateau(monitor='val_loss', factor=0.2, patience=5, min_lr=0.0001)

# Train the model
history = model.fit(
    X_train,
    y_train,
    epochs=100,
    batch_size=32,
    validation_split=0.2,
    callbacks=[early_stopping, reduce_lr],
    verbose=0 # Suppress verbose output during training
)

print("ANN Model training complete.")

# Plot training history
# Extract data from history object
acc = history.history['accuracy']
val_acc = history.history['val_accuracy']
loss = history.history['loss']
val_loss = history.history['val_loss']
epochs_range = range(len(acc))

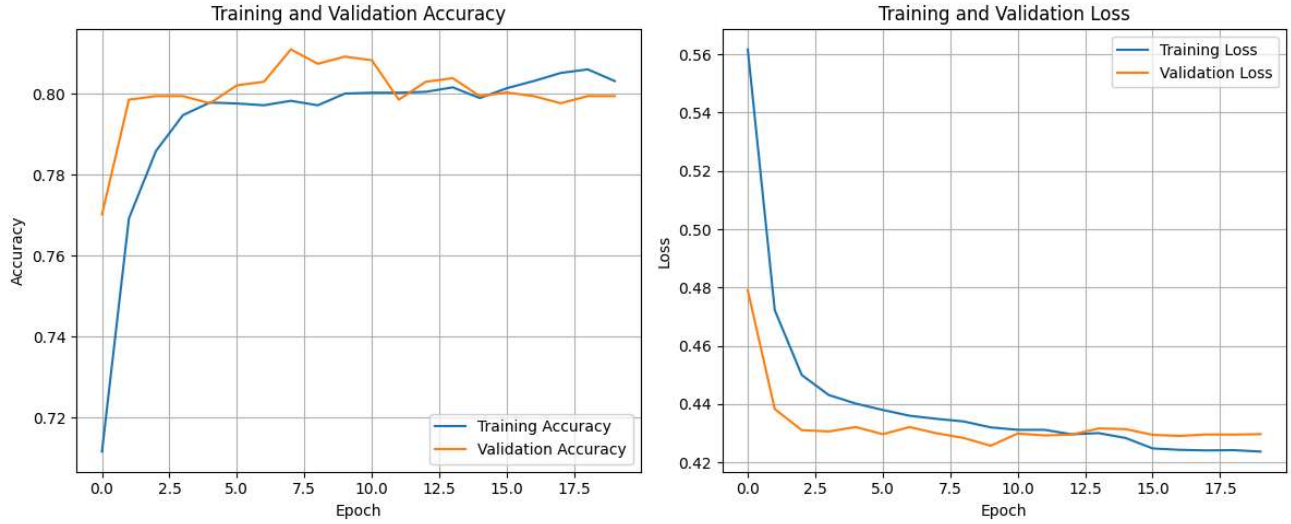
plt.tight_layout()
plt.show()
```

```
ANN Model training complete.
```



Evaluating ANN Model Performance

this requires predicting churn probabilities and class labels on the test dataset, and then computing accuracy, classification report, and confusion matrix.

```
from sklearn.metrics import accuracy_score, classification_report, confusion_matrix
import numpy as np

# 1. Predict churn probabilities on the test set
y_pred_proba = model.predict(X_test)

# 2. Convert probabilities into binary class labels using a threshold of 0.5
y_pred = (y_pred_proba > 0.5).astype(int)

# 3. Calculate and print the overall accuracy
accuracy = accuracy_score(y_test, y_pred)
print(f"Overall Accuracy: {accuracy:.4f}")

# 4. Generate and print a classification report
class_report = classification_report(y_test, y_pred)
print("\nClassification Report:")
print(class_report)

# 5. Compute the confusion matrix
conf_matrix = confusion_matrix(y_test, y_pred)
print("\nConfusion Matrix:")
print(conf_matrix)
```

```
45/45 ━━━━━━━━━━━━━━━━━━━━ 1s 11ms/step
Overall Accuracy: 0.7622

Classification Report:
              precision    recall  f1-score   support

           0       0.81      0.88      0.85      1042
           1       0.56      0.42      0.48       367

    accuracy                           0.76      1409
   macro avg       0.69      0.65      0.66      1409
weighted avg       0.75      0.76      0.75      1409
```

```
Confusion Matrix:
[[919 123]
 [212 155]]
```

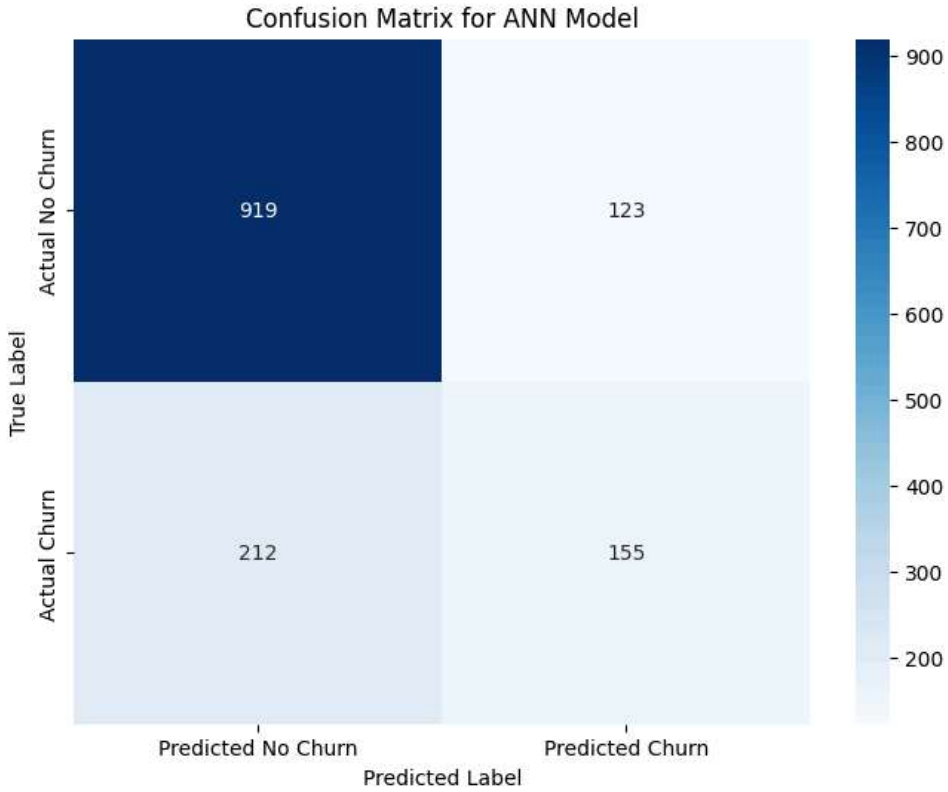
Reasoning: I have already computed the confusion matrix. Now, I need to visualize it as a heatmap and then calculate and plot the ROC curve with AUC, as per the subtask instructions.

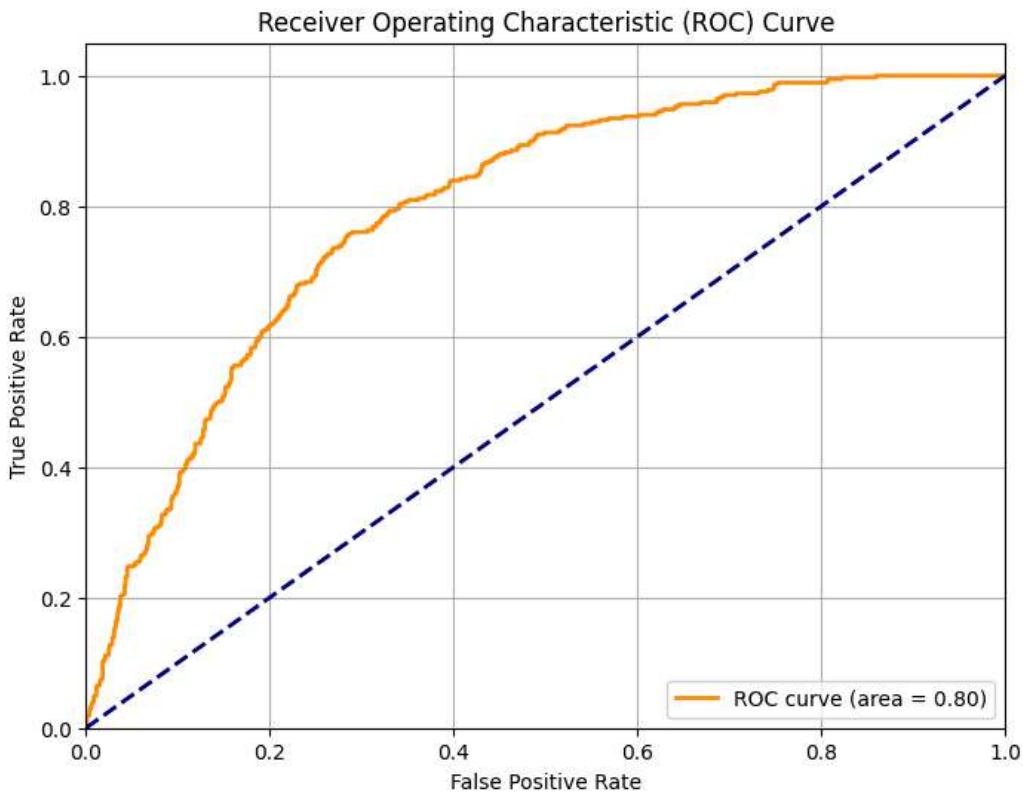
```
import seaborn as sns
import matplotlib.pyplot as plt
from sklearn.metrics import roc_curve, roc_auc_score

# 6. Visualize the confusion matrix as a heatmap
plt.figure(figsize=(8, 6))
sns.heatmap(conf_matrix, annot=True, fmt='d', cmap='Blues',
            xticklabels=['Predicted No Churn', 'Predicted Churn'],
            yticklabels=['Actual No Churn', 'Actual Churn'])
plt.title('Confusion Matrix for ANN Model')
plt.xlabel('Predicted Label')
plt.ylabel('True Label')
plt.show()

# 7. Calculate FPR, TPR, and AUC score for ROC curve
fpr, tpr, thresholds = roc_curve(y_test, y_pred_proba)
auc_score = roc_auc_score(y_test, y_pred_proba)

# 8. Plot the ROC curve
plt.figure(figsize=(8, 6))
plt.plot(fpr, tpr, color='darkorange', lw=2, label=f'ROC curve (area = {auc_score:.2f})')
plt.plot([0, 1], [0, 1], color='navy', lw=2, linestyle='--')
plt.xlim([0.0, 1.0])
plt.ylim([0.0, 1.05])
plt.xlabel('False Positive Rate')
plt.ylabel('True Positive Rate')
plt.title('Receiver Operating Characteristic (ROC) Curve')
plt.legend(loc='lower right')
plt.grid(True)
plt.show()
```





Analysis of ANN Model Performance

Recall for the 'Churn' Class (Label 1): From the classification report, the recall for class 1 (churn) is approximately 0.42. This means that the model correctly identifies only 42% of actual churning customers. In other words, for every 100 customers who actually churn, our model only predicts 42 of them will churn, missing 58 of them. This is a significant limitation, as missing actual churners (false negatives) means the business loses opportunities to intervene and retain those customers.

Trade-off Between False Positives and False Negatives (Business Implications):

- **Confusion Matrix:**
  - **True Negatives (TN):** 919 customers were correctly identified as non-churners.
  - **False Positives (FP):** 123 customers were incorrectly identified as churners (Type I error). These are customers who would not churn but are flagged for intervention. The cost here could be unnecessary marketing efforts or special offers. While these might annoy some customers or incur costs, they generally don't lead to direct loss of revenue from actual churn.
  - **False Negatives (FN):** 212 customers were incorrectly identified as non-churners (Type II error). These are customers who actually churn but the model failed to predict it. This is a critical error in churn prediction, as it represents lost revenue and missed opportunities for retention campaigns.
  - **True Positives (TP):** 155 customers were correctly identified as churners.
- **ROC Curve and AUC:**
  - The Area Under the Curve (AUC) is approximately 0.80. An AUC of 0.80 suggests that the model has a reasonably good ability to distinguish between churning and non-churning customers, better than a random classifier (AUC = 0.5). However, the specific operating point chosen (threshold of 0.5) significantly impacts the precision and recall values.
  - The ROC curve shows the trade-off between True Positive Rate (TPR, or recall) and False Positive Rate (FPR). To increase recall for churners, we might need to accept a higher FPR. If the cost of a false negative (missing a churner) is much higher than the cost of a false positive (offering retention incentives to a non-churner), the business might choose a lower probability threshold, which would shift the operating point on the ROC curve to the top-left, increasing TPR at the expense of FPR.

Business Implications:

Given the relatively low recall for churners (42%), the current model might not be optimal for a business strategy heavily focused on proactive customer retention. If the primary goal is to minimize churn at all costs, the business might prefer a model with higher recall, even if it comes with a higher false positive rate. Sending retention offers to 123 non-churners (false positives) costs money, but failing to identify 212 actual churners (false negatives) likely costs significantly more in lost revenue. Therefore, the current model's balance of errors might need to be adjusted by tuning the classification threshold to prioritize higher recall for the churn class.

Summary of Overall Performance:

The ANN model achieves an overall accuracy of 76.22% and an AUC score of 0.80, which indicates a decent ability to classify customers. However, its performance in identifying the minority class (churners) is weak, with a recall of only 42%. While the precision for churners (56%) is moderate, the low recall suggests that the model is missing a large number of actual churners. For churn prediction, often recall for the churn class is prioritized to enable timely interventions. This model, in its current configuration, would be useful for identifying some churners, but there's a substantial opportunity cost due to the high number of false negatives. Further optimization, potentially by adjusting the classification threshold or exploring more sophisticated models or sampling techniques, would be beneficial to improve the identification of at-risk customers.

Analyze Feature Importance

Reasoning: The subtask requires analyzing feature importance using an interpretable model. I will use `LogisticRegression` due to its interpretability (coefficients directly indicate feature importance) and train it on the scaled training data. Then I will display the top features influencing churn.

```
from sklearn.linear_model import LogisticRegression
import pandas as pd

# Train a Logistic Regression model on the scaled data
# We use X_data.columns to get the original feature names
# C=0.1 to add some regularization, solver='liblinear' is good for small datasets and L1/L2 regularization
logistic_model = LogisticRegression(solver='liblinear', random_state=42, C=0.1)
```

```
logistic_model.fit(X_train, y_train)

# Get feature coefficients
feature_importance = pd.DataFrame({
    'Feature': X_data.columns,
    'Coefficient': logistic_model.coef_[0]
})

# Sort by absolute coefficient value to see most impactful features
feature_importance['Abs_Coefficient'] = abs(feature_importance['Coefficient'])
feature_importance = feature_importance.sort_values(by='Abs_Coefficient', ascending=False)

print("Top Features by Importance (Logistic Regression Coefficients):")
display(feature_importance.head(10))

print("\nTop Positive Drivers of Churn (features with highest positive coefficients):")
display(feature_importance.sort_values(by='Coefficient', ascending=False).head(5))

print("\nTop Negative Drivers of Churn (features with lowest negative coefficients):")
display(feature_importance.sort_values(by='Coefficient', ascending=True).head(5))
```

```
Top Features by Importance (Logistic Regression Coefficients):
```

Explanation of Top Feature Importance (Logistic Regression Coefficients)

Logistic Regression coefficients indicate the strength and direction of the relationship between each feature and the log-odds of churn. Positive coefficients mean the feature increases the likelihood of churn, while negative coefficients mean it decreases the likelihood.

Top Positive Drivers of Churn:

- **MonthlyCharges (Coefficient: 0.976):** A strong positive driver. Higher monthly charges significantly increase the likelihood of customer churn. This suggests that customers perceive less value for money or find the cost prohibitive, leading them to leave.
- **SeniorCitizen (Coefficient: 0.217):** Being a senior citizen is associated with a higher likelihood of churn. This could indicate that older customers might be less tech-savvy, more sensitive to price changes, or have different needs that are not being met.
- **Cluster (Coefficient: 0.067):** The 'Cluster' feature from the K-Means clustering, while a composite, shows a positive correlation. This means that belonging to certain customer segments (clusters with higher values) slightly increases the probability of churn. Further analysis of these specific clusters would reveal the underlying reasons.
- **Contract_Month-to-month (Coefficient: 0.052):** Customers on month-to-month contracts are more likely to churn. This is a very common finding, as these contracts offer flexibility with no long-term commitment, making it easier for customers to switch providers.
- **MultipleLines (Coefficient: 0.035):** Having multiple phone lines slightly increases the likelihood of churn. This might be counter-intuitive, but it could suggest that customers with more complex service bundles are more likely to seek better integrated or more cost-effective solutions elsewhere.

Top Negative Drivers of Churn:

- **tenure (Coefficient: -1.342):** The strongest negative driver. Longer customer tenure significantly decreases the likelihood of churn. This indicates customer loyalty: the longer a customer stays, the less likely they are to leave. This is a critical retention factor.
- **PhoneService (Coefficient: -0.238):** Having phone service reduces the likelihood of churn. This could imply that customers who subscribe to basic phone service are generally more stable or have different needs compared to those
